

## Rapid Assessment Reference Condition Model

The Rapid Assessment is a component of the LANDFIRE project. Reference condition models for the Rapid Assessment were created through a series of expert workshops and a peer-review process in 2004-2005. For more information, please visit [www.landfire.gov](http://www.landfire.gov). Please direct questions to [helpdesk@landfire.gov](mailto:helpdesk@landfire.gov).

### Potential Natural Vegetation Group (PNVG):

R1ASPN

Aspen with Conifer

#### Geographic Range

Sites that support aspen are common at elevations exceeding about 5000 feet in the Modoc Plateau, Warner Mountains, and Sierra Nevada. Aspen is found in smaller patches in the Klamath Mountains, and is rare in the mountains of southern California.

#### Biophysical Site Description

At lower elevations throughout its range in California (3500-6500'), the aspen forest type is associated with sites with added moisture, i.e., azonal wet sites. These sites are often close to streams and lakes. Other sites include meadow edges, rock reservoirs, springs and seeps. Terrain can be simple to complex. At these lower elevations, topographic conditions for this type tends toward positions resulting in relatively colder, wetter conditions within the prevailing climate, e.g., ravines, north slopes, wet depressions, etc. At higher elevations, (6500' +) more diverse combinations are possible because of generally wetter, colder climates. At these higher elevations, aspen forest type can occur in the riparian settings mentioned above as well as on sites subject to snowdrift accumulation, slight depressions, and sites appear to be zonal or close to zonal. Aspen sites fall into two distinct categories at the higher elevations: those riparian-associated sites that are not likely to be succeeded by conifers ("meadow aspen"), and those sites where conifers such as JUOC, ABCO, ABMA, PICO1 can succeed aspen and eventually dominate in the absence of fire or logging disturbance ("upland aspen"). Soil temperature regimes are usually frigid to cryic, with mesic soil temperature regimes being much less common. The VDDT model associated with this description models the "upland" aspen type with conifer succession potential.

#### Vegetation Description

Sites in the "HRV" aspen existing vegetation state, with deep soils: stands are dominated by aspen trees in a range of size classes. Tree canopy cover in reference condition stands can easily exceed 85%. Understory graminoid and forb vegetation is rich and diverse in deep soil sites because of high water retention and bountiful soil nutrients. Soils on the deep sites usually have mollic epipedons, high root

\*Dominant and Indicator Species are from the NRCS PLANTS database. To check a species code, please visit <http://plants.usda.gov>.

density, and biologically active litter components. At least 500 aspen suckers 5-15' tall will be present in HRV conditions. Lack of suckers or stems in the 15-30' tall class is representative of potentially unsustainable conditions for aspen. Another potentially unsustainable condition occurs if sagebrush cover (various species but usually Mountain Big Sagebrush) or conifer cover (JUOC, PIPO, ABCO, ABMA, PICO1 are possibilities) exceeds 10%.

**Disturbance Description**

Meadow sites supporting the aspen type are maintained by occasional stand replacing fire, and reference conditions are severely impaired by improperly timed grazing. Upland sites supporting the aspen type are maintained by disturbances that allow regeneration from below-ground suckers such as stand replacement fires. Upland aspen clones are impaired or eliminated by conifer ingrowth and overtopping and to a lesser extent by disturbances such as ill-timed grazing. If aboveground aspen on upland sites disappears (site overtaken by conifers) then the site has probably shifted to a conifer PNVG and restoration to an aspen state is not a viable pathway. In a reference condition scenario, a few stands will advance toward conifer dominance, but much fewer than in many current scenarios where fire frequency is reduced from reference conditions.

**Adjacency or Identification Concerns**

This model considers sites that support the "upland aspen type" as opposed to the "meadow aspen type". The "meadow aspen type" PNVG seems to be covered by the R3ASPN model.

**Scale Description**

**Sources of Scale Data**  Literature  Local Data  Expert Estimate

Patch sizes range in the 10s to 100s of acres.

**Issues/Problems**

**Model Evolution and Comments**

Removed -10 year relative age in model state C - it is inconsistent with modeling rules and is unnecessary given a 200 year TSD. Suggested reviewers: Dale Bartos, Wayne Shephard, Robert Campbell - did not respond to requests for review.

<b>Succession Classes</b>

**Fire Regime Group: 4**

I: 0-35 year frequency, low and mixed severity  
 II: 0-35 year frequency, replacement severity  
 III: 35-200 year frequency, low and mixed severity  
 IV: 35-200 year frequency, replacement severity  
 V: 200+ year frequency, replacement severity

**Historical Fire Size (acres)**

Avg:  
 Min:  
 Max:

**Fire Intervals (FI):**

Fire interval is expressed in years for each fire severity class and for all types of fire combined (All Fires). Average FI is the central tendency modeled. Minimum and maximum show the relative range of fire intervals, if known. Probability is the inverse of fire interval in years and is used in reference condition modeling. Percent of all fires is the percent of all fires in that severity class. All values are estimates and not precise.

**Sources of Fire Regime Data**
